

Exercise 1

(A) Interprets of parameters:

 n : The number of steps per unit time; T : The total observe time; μ : The risk premium (mean) of holding asset during a time unit (day); σ : The standard deviation of asset price during a time unit (day).**Better to compute out the annualized result, at least one (-0.1)**Assuming the trading time for a year is T , then we have:

$$E(X_T^n) = T * E(X_1^n) = T\mu \quad (1)$$

$$sd(X_T^n) = \sqrt{Var(X_T^n)} = \sqrt{T * Var(X_1^n)} = \sqrt{T}\sigma \quad (2)$$

(B) In order to stimulate the continuous time process of asset price P , we need to decompose the continuous time into small time interval (step):

$$X_i = X_{i-1} + \mu\Delta_n + \sigma\sqrt{\Delta_n}Z_i \quad (3)$$

then we have:

$$X_i - X_{i-1} = \mu\Delta_n + \sigma\sqrt{\Delta_n}Z_i \quad (4)$$

$$X_n^T = \sum_{i=1}^{nT/\Delta_n} (\mu\Delta_n + \sigma\sqrt{\Delta_n}Z_i) \quad (5)$$

Here Z_i are identical independent normal distribution, that is $Z_i \sim \mathcal{N}(0, 1)$ for $i = 1, 2, \dots, nT$.To construct X_n^T :

- (i) Construct a series number from the standard normal distribution;
- (ii) Adding each component in equation(5);
- (iii) Converting the log-price to prices.

Here is the plot of time series prices:

I love your formulas and steps, but please focus more on the interpretation next time.

Figure 1: Time Series Prices (Gaussian Diffusion with Constant Coefficients)

From the figure, we can see the price range is (260,340) and the price fluctuates a lot.

The **MATLAB** code:

```
1 function [x] = GD_c(T,n,c,u,x0)
2 % simulate a Gaussian diffusion model with CONSTANT coefficient
3 % T is total observe time
4 % x is the array of log-price of asset between time 0~T
5 % x0 is the initial value of xt(at t=0)
6 % n is the number of observations in every unit of time
7 % c is the standard variance of log-price
8 % u is the mean of asset's log-price
9     x=[];
10    x(1)=x0; % initial value of x(at t=0)
11    delta_t=1/n; % delta_t is the time gap between every observation
12    for i=1:T*n % observation number from 1 to T*n
13        z=normrnd(0,1); % construct random variable from standard normal
14        x(i+1)=x(i)+u*delta_t+sqrt(c*delta_t)*z; % calculate x(i+1) by
15        iteration
16    end
17 end
```

```
1 % -----EXERCIZE #1(GAUSSIAN DIFFUSION MODEL WITH CONSTENT COEFFICIENTS)-----
2 % SET PARAMETERS
3 n=80;
4 T=1.25*252;
5 u=0.03872/100;
6 c=0.011^2;
7 x0=log(292.58);
8
9 % PART B(STIMULATE MODEL)
10 X1=GD_c(T,n,c,u,x0) % calculate value of Xt
11 P1=exp(X1); % convert log-price to price
12 t=0:1/n:T; % construct observation time series
13 f1=figure('name','Time Series of Prices(GAUSSIAN DIFFUSION MODEL WITH
    CONSTANT COEFFICIENTS)');
14 plot(t,P1);% plot time series of prices
15 xlabel('Time(day)');
16 ylabel('Price');
17 xlim([0,T]);
18 % -----END OF EXERCIZE #1-----
```

Exercise 2

(A) Interprets of parameters:

λ : The density of Poisson distribution during a time unit(per day);

σ_j : The standard deviation of step jump.

Here σ is the standard deviation of daily jump, while σ_j is the standard variance of jump of every step. Since every day is divided into n steps, we need to convert daily standard deviation to step standard deviation by divided \sqrt{n} .

(B) To construct compound Poisson process J_i :

(i) Produce a Poisson distribution with density λT to product the jump number N ;

(ii) Produce jump time by producing N random number from $\text{Unif} \sim (0, T)$;

(iii) Produce jump size by producing N random number from $\mathcal{N}(0, 1)$;

Here is the plot of time series prices:

Figure 2: Time Series of Exponential Jump

From the figure, we can see there are total 12 times of jump during our observation (from time=0 to 315). The (exponential) jump size range from 0.85 to 1.03. Among these 12 jumps, 7 of them are upside jumps, while 5 of them are downside jumps.

The **MATLAB** code:

```

1 function [j] =jump(lamda,T,n,sigma)
2 % simulate a Compound Poisson Process
3 % T is total observe time
4 % j is the array of accumulated jump at a specifit time from 0 to T
5 % n is the number of observations in every unit of time
6 % sigma is the standard variance of jump
7 j=[];
8 j(1)=0; % the initial value of jump (at t=0)
9 N=random('poisson',lamda*T); % the number of total jumps follow a Poisson
    distribution with density lamda*T
10 t=random('uniform',0,T,N,1); % the time of jumps follow a uniform
    distribution from (0,T)
11 y=random('normal',0,(18*sigma)/sqrt(n),N,1);% the size of jumps follow
    normal distribution with mean=0,sd=(18*sigma)/sqrt(n)
12 for i=1:T*n
13     k=0;
14     for h=1:N % this loop aims at calculate the jumps which happens during
        time period ((i-1)/n,i/n)
15         p=y(h)*indic((i-1)/n,i/n,t(h));
16         k=k+p;
17     end
18     j(i+1)=j(i)+k;% accumulate jumps from time 0 to (i+1)/n
19 end
20 end

1 % -----EXCERSIZE #2(COMPOUND POISSON PROCESS)-----
2 % SET PARAMETERS
3 n=80;
4 T=1.25*252;
5 sigma=0.011;
6 lamda=15/252;
7
8 % PART B(STIMULATE MODEL)
9 J1=jump(lamda,T,n,sigma); % calculate value of Jt
10 e_J1=exp(J1);% make exponential for log-jump
11 t=0:1/n:T; % construct observation time series
12 f2=figure('name','Time Series of Exponential Jump(COMPOUND POISSON PROCESS)'
    );
13 plot(t,e_J1);% plot of the simulated compound Poisson process
14 xlabel('Time(day)');
15 ylabel('Stimulation of Exponential Jump');
16 xlim([0,T]);
17 % -----END OF EXCERCIZE #2-----

```

Exercise 3

Not clear on the reason of combining. Better to look at the equation of jump-diffusion

- (A) Both expression 1 and 4 are correct. Expression 1 is the log-price (with log-jump) of asset, while expression 4 is the price (with jump) of asset.
- (B) Here use expression 4 to calculate the price (with jump) of asset. Following is the plot of time series prices:

Figure 3: Time Series of Price with Jump

Compare to figure in Exercise 1, we can see the price range doesn't change a lot, but the fluctuation of price has increased.

I think you could comment more on the range of value and the trend among time (-0.1)

The **MATLAB** code:

```

1  % ———EXCERCIZE #3(JUMP DIFFUSION MODEL WITH CONSTENT COEFFICIENTS)———
2  % SET PARAMETERS
3  n=80;
4  T=1.25*252;
5  u=0.03872/100;
6  c=0.011^2;
7  x0=log(292.58);
8  sigma=0.011;
9  lamda=15/252;
10
11 % PART B(STIMULATE MODEL)
12 X1=GD_c(T,n,c,u,x0); % calculate value of Xt
13 J1=jump(lamda,T,n,sigma); % calculate value of Jt

```

```
14 |
15 | t=0:1/n:T; % construct observation time series
16 | X2_with_jump=X1+J1; %calculate log-price with jump
17 | P2_with_jump=exp(X2_with_jump);%convert log-price to price
18 | f3=figure('name','Time Series of Price with Jump(JUMP DIFFUSION MODEL WITH
    |         CONSTANT COEFFICIENTS)');
19 | plot(t,P2_with_jump);% plot of time series price
20 | xlabel('Time(day)');
21 | ylabel('Price with jump');
22 | xlim([0,T]);
23 | %-----END OF EXCERCIZE #3-----
```

Exercise 4

(A) Interprets of parameters:

ρ : The rate of convergence; **Please be specific: convergence to the average volatility**

μ_c : The mean of step price volatility.

σ_c : The volatility of step price volatility.

(B) To construct stochastic variance process c_j :

(i) Construct a series number from the standard normal distribution;

(ii) Compute each c_j by iteration;

Here is the plot of time series prices:

Figure 4: Stimulation of Annual C_t
Please comment more on the path of variance (-0.1)

From the figure, we can see at time around 40, 100, 180 and 300, there are large jump of C_t .

(C) To construct high frequency log-price X_j :

(i) Construct a series number from the standard normal distribution;

(ii) Use c_j to compute each X_j by iteration;

Here is the plot of time series prices:

Figure 5: Stimulated of Time Series Price X_t (Use High Frequency Samples)

From the figure, those we can see at time around 40, 100 and 180 and 300, X_t has large jump, too.

More comments (-0.1)

(D) Here is the plot of time series log-return:

Figure 6: Time Series Log-return (Use High Frequency Samples)

From the figure, those we can see at time around 40, 100 and 180 and 300, where X_t

has large jump, the price log-return fluctuates a lot, so well as the log-return in their neighbor time interval. We can find the pattern of volatility clustering.

(E) Here is the plot of time series log-return with coarser frequency sample:

Figure 7: Time Series Log-return (Use Coarser Frequency Samples)

From the figure we can find the pattern of volatility clustering is more obvious than the case using high frequency sample.

(F) Here are the plots of stochastic volatility with different rate of convergence ρ :

Great work, but better to put different paths into a same figure (+0.4)

Figure 8: Stochastic Volatility C_t with $\rho = 0.03$ Figure 9: Stochastic Volatility C_t with $\rho = 0.1$

From the figure, we can find as the rate of convergence ρ increases, the pattern that price stochastic volatility C_t fluctuates around its mean becomes more obvious, that is, the price stochastic volatility C_t converges at a faster speed.

(G) Here are the plots of stochastic volatility with different volatility σ_c :

Great work, but better to put different paths into a same figure (+0.4)

Figure 10: Stochastic Volatility C_t with $\sigma_c = 0.005$ Figure 11: Stochastic Volatility with $\sigma_c = 0.01$

From the figure, we can find as the stochastic volatility with different volatility σ increases from 0.005 to 0.01, the range of stochastic volatility C_t has doubled from $(\frac{\mu_c}{2}, 70)$ to $(\frac{\mu_c}{2}, 140)$, the volatility of C_t increases.

The **MATLAB** code:

```
1 function [c] = JD_sv_ct(ne,T,l,u_c,sigma_c,c0)
2 % simulate stochastic variance process {ct} in a Jump-diffusion model
```

```

3 % c is the array of ct between t vary from 0~T
4 % T is total observe time
